

143A: Principles of Operating Systems

Lecture 09: Interrupts and Exceptions

Anton Burtsev
November, 2018

Why do we need interrupts?

Remember:
hardware interface is designed to help OS

Why do we need interrupts?

- Two main use cases:
 - [Synchronous] Something bad happened and OS needs to fix it
 - Program tries to access an unmapped page (OS maps the page if its on disk)
 - [Asynchronous] Notifications from external devices
 - Network packet arrived (OS will copy the packet from temporary buffer in memory (to avoid overflowing) and may switch to a process waiting on that packet)
 - Timer interrupt (OS may switch to another process)
- A third, special, use-case
 - [It's also synchronous] For a while an interrupt, i.e., int 0xXX instruction, was used as a mechanism to transfer control flow from user-level to kernel in a secure manner
 - In other words, to implement system calls
 - Now, a faster mechanism is available (sysenter)

How do we handle an interrupt?

Handling interrupts and exceptions

- In both synchronous and asynchronous cases the CPU follows the **same procedure**
 - Stop execution of the current program
 - Start execution of a handler
 - Processor accesses the handler through an entry in the Interrupt Descriptor Table (IDT)
- Each interrupt is defined by a number
 - E.g., 14 is pagefault, 3 debug
 - This number is an index into the interrupt table (IDT)

There might be two cases

- Interrupt requires **no change** of privilege level
 - i.e., the CPU runs kernel code (privilege level 0) when
 - a timer interrupt arrives, or
 - kernel tries to access an unmapped page
- Interrupt **changes** privilege level
 - i.e., the CPU runs **user** code (privilege level 3) when
 - a timer interrupt arrives, or
 - User code tries to access an unmapped page

Case #1: Interrupt path no change in privilege level

- e.g., we're already running in the kernel

47

IDTR Register

Interrupt descriptor table (IDT)

- Is pointed by the IDTR register
 - Virtual address
- OS configures the value and loads it into the register (normally during boot)

Interrupt descriptor

Interrupt descriptor

- We will walk through these fields gradually
 - For now we care about vector offset
 - Pointer to the interrupt handler

Interrupt handlers

- Just plain old code in the kernel
- The IDT stores a pointer to the right handler routine

Interrupt path

Processing of interrupt (same PL)

1. Push the current contents of the EFLAGS, CS, and EIP registers (in that order) on the stack
2. Push an error code (if appropriate) on the stack
3. Load the segment selector for the new code segment and the new instruction pointer (from the interrupt gate or trap gate) into the CS and EIP registers
4. If the call is through **an interrupt gate**, clear the IF flag in the EFLAGS register (**disable further interrupts**)
5. Begin execution of the handler

Stack Usage with No Privilege-Level Change

Interrupted Procedure's and Handler's Stack

Interrupt path

Processing of interrupt (cross PL)

- Need to change privilege level...

Detour:
What are those privilege levels?

Recap: Can a process overwrite kernel memory?

Privilege levels

- Each segment has a privilege level
 - DPL (descriptor privilege level)
 - 4 privilege levels ranging 0-3

Privilege levels

- Each segment has a privilege level
 - DPL (descriptor privilege level)
 - 4 privilege levels ranging 0-3

Privilege levels

- Currently running code also has a privilege level
 - “Current privilege level” (CPL): 0-3
 - It is saved in the %cs register
 - It was loaded there when the descriptor for the currently running code was loaded into %cs

Privilege level transitions

- CPL can access only less privileged segments
 - E.g., 0 can access 1, 2, 3
- Some instructions are “privileged”
 - Can only be invoked at CPL = 0
 - Examples:
 - Load GDT
 - MOV <control register>
 - E.g. reload a page table by changing CR3

Xv6 example: started boot (no CPL yet)

Xv6 example: prepare to load GDT entry #1

Privilege levels

- Each segment has a privilege level
 - DPL (descriptor privilege level)
 - 4 privilege levels ranging 0-3

Now CPL=0. We run in the kernel

iret: return to user, load GDT #4

Run in user, CPL=3

Real world

- Only two privilege levels are used in modern OSes:
 - OS kernel runs at 0
 - User code runs at 3
- This is called “flat” segment model
 - Segments for both 0 and 3 cover entire address space
- But then... how the kernel is protected?

Real world

- Only two privilege levels are used in modern OSes:
 - OS kernel runs at 0
 - User code runs at 3
- This is called “flat” segment model
 - Segments for both 0 and 3 cover entire address space
- But then... how the kernel is protected?
 - **Page tables**

Page table: user bit

- Each entry (both Level 1 and Level 2) has a bit
 - If set, code at privilege level 3 can access
 - If not, only levels 0-2 can access
- Note, only 2 levels, not 4 like with segments
- All kernel code is mapped with the user bit clear
 - This protects user-level code from accessing the kernel

End of detour:
Back to handling interrupts

Recap: interrupt path, no PL change

Processing of an interrupt when change of a privilege level is required

Processing of interrupt (cross PL)

- Assume we're at CPL =3 (user)

Interrupt descriptor (an entry in the IDT)

- Interrupt is allowed if...
 - current privilege level (CPL) is less or equal to descriptor privilege level (DPL)
- The kernel protects device interrupts from user

Interrupt descriptor (an entry in the IDT)

- Note that this new segment can be more privileged
 - E.g., CPL = 3, DPL = 3, new segment can be PL = 0
 - This is how user-code (PL=3) transitions into kernel (PL=0)

Interrupt path

Stack

- Can we continue on the same stack?

Stack

- But how hardware knows where it is?

Interrupt
Vector #

Timer: IRQ0 -> vector 32

GDT
NULL: 0x0
KCODE: 0 - 4GB
KDATA: 0 - 4GB
K_CPU: 4 bytes
CODE: 0 - 4GB
DATA: 0 - 4GB
TSS: sizeof(ts)

IDT

CS : HANDLER ADDR
...

Page table
Level 1

0 - 4MB
4 - 8MB
...
2GB - 2GB + 4MB

→

0 - 4K
4K - 8K
...
(4MB-4K) - 4MB

Kernel
code

vector32

TSS: Task State Segment (yet another table)

Task State Segment

- Another magic control block
 - Pointed to by special task register (TR)
- Lots of fields for rarely-used features
- A feature we care about in a modern OS:
 - Location of kernel stack (fields SS/ESP)
 - Stack segment selector
 - Location of the stack in that segment

Processing of interrupt (cross PL)

1. Save ESP and SS in a CPU-internal register
- 2. Load SS and ESP from TSS**
3. Push user SS, user ESP, user EFLAGS, user CS, user EIP onto new stack (kernel stack)
4. Set CS and EIP from IDT descriptor's segment selector and offset
5. If the call is through an interrupt gate clear some EFLAGS bits
6. Begin execution of a handler

Stack Usage with Privilege-Level Change

Interrupted Procedure's
Stack

ESP Before
Transfer to Handler

Handler's Stack

ESP After
Transfer to Handler

Stack Usage with No Privilege-Level Change

Interrupted Procedure's and Handler's Stack

Complete interrupt path

Return from an interrupt

- Starts with IRET
 - 1. Restore the CS and EIP registers to their values prior to the interrupt or exception
 - 2. Restore EFLAGS
 - 3. Restore SS and ESP to their values prior to interrupt
 - This results in a stack switch
 - 4. Resume execution of interrupted procedure

Interrupt descriptor table (IDT)

x86 interrupt descriptor table

Vector No.	Mnemonic	Description	Source
0	#DE	Divide Error	DIV and IDIV instructions.
1	#DB	Debug	Any code or data reference.
2		NMI Interrupt	Non-maskable external interrupt.
3	#BP	Breakpoint	INT 3 instruction.
4	#OF	Overflow	INTO instruction.
5	#BR	BOUND Range Exceeded	BOUND instruction.
6	#UD	Invalid Opcode (UnDefined Opcode)	UD2 instruction or reserved opcode. ¹
7	#NM	Device Not Available (No Math Coprocessor)	Floating-point or WAIT/FWAIT instruction.
8	#DF	Double Fault	Any instruction that can generate an exception, an NMI, or an INTR.
9	#MF	CoProcessor Segment Overrun (reserved)	Floating-point instruction. ²
10	#TS	Invalid TSS	Task switch or TSS access.
11	#NP	Segment Not Present	Loading segment registers or accessing system segments.
12	#SS	Stack Segment Fault	Stack operations and SS register loads.
13	#GP	General Protection	Any memory reference and other protection checks.
14	#PF	Page Fault	Any memory reference.
15		Reserved	
16	#MF	Floating-Point Error (Math Fault)	Floating-point or WAIT/FWAIT instruction.
17	#AC	Alignment Check	Any data reference in memory. ³
18	#MC	Machine Check	Error codes (if any) and source are model dependent. ⁴
19	#XM	SIMD Floating-Point Exception	SIMD Floating-Point Instruction ⁵
20-31		Reserved	
32-255		Maskable Interrupts	External interrupt from INTR pin or INT <i>n</i> instruction.

Vector No.	Mnemonic	Description	Source
0	#DE	Divide Error	DIV and IDIV instructions.
1	#DB	Debug	Any code or data reference.
2		NMI Interrupt	Non-maskable external interrupt.
3	#BP	Breakpoint	INT 3 instruction.
4	#OF	Overflow	INTO instruction.
5	#BR	BOUND Range Exceeded	BOUND instruction.
6	#UD	Invalid Opcode (UnDefined Opcode)	UD2 instruction or reserved opcode. ¹
7	#NM	Device Not Available (No Math Coprocessor)	Floating-point or WAIT/FWAIT instruction.
8	#DF	Double Fault	Any instruction that can generate an exception, an NMI, or an INTR.
9	#MF	CoProcessor Segment Overrun (reserved)	Floating-point instruction. ²
10	#TS	Invalid TSS	Task switch or TSS access.
11	#NP	Segment Not Present	Loading segment registers or accessing system segments.
12	#SS	Stack Segment Fault	Stack operations and SS register loads.
13	#GP	General Protection	Any memory reference and other protection checks
14	#PF	Page Fault	Any memory reference.
15		Reserved	
16	#MF	Floating-Point Error (Math Fault)	Floating-point or WAIT/FWAIT instruction.
17	#AC	Alignment Check	Any data reference in memory. ³
18	#MC	Machine Check	Error codes (if any) and source are model dependent. ⁴
19	#XM	SIMD Floating-Point Exception	SIMD Floating-Point Instruction ⁵
20-31		Reserved	
32-255		Maskable Interrupts	External interrupt from INTR pin or INT <i>n</i> instruction.

Interrupts

- Each type of interrupt is assigned an index from 0—255.
 - 0—31 are for processor interrupts fixed by Intel
 - E.g., 14 is always for page faults
- 32—255 are software configured
 - 32—47 are often used for device interrupts (IRQs)
 - Most device IRQ lines can be configured
 - Look up APICs for more info (Ch 4 of Bovet and Cesati)
 - 0x80 issues system call in Linux
 - Xv6 uses 0x40 (64) for the system call

Disabling interrupts

- Delivery of interrupts can be disabled with IF (interrupt flag) in EFLAGS register
- There is a couple of exceptions
 - Synchronous interrupts cannot be disabled
 - It doesn't make sense to disable a page fault
 - INT n – cannot be masked as it is synchronous
 - Non-maskable interrupts (see next slide)
 - Interrupt #2 in the IDT

Vector No.	Mnemonic	Description	Source
0	#DE	Divide Error	DIV and IDIV instructions.
1	#DB	Debug	Any code or data reference
2		NMI Interrupt	Non-maskable external interrupt.
3	#BP	Breakpoint	INT 3 instruction.
4	#OF	Overflow	INTO instruction.
5	#BR	BOUND Range Exceeded	BOUND instruction.
6	#UD	Invalid Opcode (UnDefined Opcode)	UD2 instruction or reserved opcode. ¹
7	#NM	Device Not Available (No Math Coprocessor)	Floating-point or WAIT/FWAIT instruction.
8	#DF	Double Fault	Any instruction that can generate an exception, an NMI, or an INTR.
9	#MF	CoProcessor Segment Overrun (reserved)	Floating-point instruction. ²
10	#TS	Invalid TSS	Task switch or TSS access.
11	#NP	Segment Not Present	Loading segment registers or accessing system segments.
12	#SS	Stack Segment Fault	Stack operations and SS register loads.
13	#GP	General Protection	Any memory reference and other protection checks.
14	#PF	Page Fault	Any memory reference.
15		Reserved	
16	#MF	Floating-Point Error (Math Fault)	Floating-point or WAIT/FWAIT instruction.
17	#AC	Alignment Check	Any data reference in memory. ³
18	#MC	Machine Check	Error codes (if any) and source are model dependent. ⁴
19	#XM	SIMD Floating-Point Exception	SIMD Floating-Point Instruction ⁵
20-31		Reserved	
32-255		Maskable Interrupts	External interrupt from INTR pin or INT <i>n</i> instruction.

Nonmaskable interrupts (NMI)

- Delivered even if IF is clear, e.g. interrupts disabled
 - CPU blocks subsequent NMI interrupts until IRET
- Sources
 - External hardware asserts the NMI pin
 - Processor receives a message on the system bus, or the APIC serial bus with NMI delivery mode
- Delivered via vector #2

System calls

Software interrupts can be used to implement system calls

- The int N instruction provides a secure mechanism for kernel invocation
 - i.e., user can enter the kernel
 - But through a well-defined entry point
 - System call handler
- Xv6 uses vector 0x40 (or 64)
 - You can choose any other unused vector
 - Linux uses 0x80
 - Well now it uses sysenter instead of int 0x80 as it is faster

System call path

```
3316 void
3317 tvinit(void)
3318 {
3319     int i;
3320
3321     for(i = 0; i < 256; i++)
3322         SETGATE(idt[i], 0, SEG_KCODE<<3, vectors[i], 0);
3323     SETGATE(idt[T_SYSCALL], 1, SEG_KCODE<<3,
3324                                         vectors[T_SYSCALL], DPL_USER);
3325     initlock(&tickslock, "time");
3326 }
```

Initialize IDT

- `tvinit()` is called from `main()`

```
3316 void
3317 tvinit(void)
3318 {
3319     int i;
3320
3321     for(i = 0; i < 256; i++)
3322         SETGATE(idt[i], 0, SEG_KCODE<<3, vectors[i], 0);
3323     SETGATE(idt[T_SYSCALL], 1, SEG_KCODE<<3,
3324                                         vectors[T_SYSCALL], DPL_USER);
3325     initlock(&tickslock, "time");
3326 }
```

Initialize IDT

- System call interrupt vector (T_SYSCALL)

Protection

- Generally user code cannot invoke int X
 - i.e., can't issue int 14 (a page fault)
 - OS configures the IDT in such a manner that invocation of all int X instructions besides 0x40 triggers a general protection fault exception
 - Interrupt vector 13

Remember this slide: interrupt descriptor (an entry in the IDT)

- Interrupt is allowed if...
 - current privilege level (CPL) is less or equal to descriptor privilege level (DPL)
- The kernel protects device interrupts from user

```
3316 void
3317 tvinit(void)
3318 {
3319     int i;
3320
3321     for(i = 0; i < 256; i++)
3322         SETGATE(idt[i], 0, SEG_KCODE<<3, vectors[i], 0);
3323     SETGATE(idt[T_SYSCALL], 1, SEG_KCODE<<3,
3324                                         vectors[T_SYSCALL], DPL_USER);
3325     initlock(&tickslock, "time");
3326 }
```

Initialize IDT

- A couple of important details

```
3316 void
3317 tvinit(void)
3318 {
3319     int i;
3320
3321     for(i = 0; i < 256; i++)
3322         SETGATE(idt[i], 0, SEG_KCODE<<3, vectors[i], 0);
3323     SETGATE(idt[T_SYSCALL], 1, SEG_KCODE<<3,
3324                                         vectors[T_SYSCALL], DPL_USER);
3325     initlock(&tickslock, "time");
3326 }
```

Initialize IDT

- Only `int T_SYSCALL` can be called from user-level

```
3316 void  
3317 tvinit(void)  
3318 {  
3319     int i;  
3320  
3321     for(i = 0; i < 256; i++)  
3322         SETGATE(idt[i], 0, SEG_KCODE<<3, vectors[i], 0);  
3323     SETGATE(idt[T_SYSCALL], 1, SEG_KCODE<<3,  
3324  
3325         vectors[T_SYSCALL], DPL_USER);  
3326 }
```

Initialize IDT

- Syscall is a “trap”
- i.e., doesn't disable interrupts

Interrupt path through the xv6 kernel

Where does IDT (entry 64) point to?

vector64:

```
pushl $0      // error code
```

```
pushl $64      // vector #
```

`jmp alltraps`

- Automatically generated
- From vectors.pl
 - `vector.S`

Kernel stack after interrupt

Kernel stack after interrupt

Call stack: vector32()
alltraps()

Syscall number

- System call number is passed in the %eax register
 - To distinguish which syscall to invoke,
 - e.g., sys_read, sys_exec, etc.
 - alltrap() saves it along with all other registers

```
3254 alltraps:  
3255 # Build trap frame.  
3256 pushl %ds  
3257 pushl %es  
3258 pushl %fs  
3259 pushl %gs  
3260 pushal  
3261  
3262 # Set up data and per-cpu segments.  
3263 movw $(SEG_KDATA<<3), %ax  
3264 movw %ax, %ds  
3265 movw %ax, %es  
3266 movw $(SEG_KCPU<<3), %ax  
3267 movw %ax, %fs  
3268 movw %ax, %gs  
3269  
3270 # Call trap(tf), where tf=%esp  
3271 pushl %esp  
3272 call trap
```

alltraps()

pusha

- An assembler instruction that saves all registers on the stack
 - https://c9x.me/x86/html/file_module_x86_id_270.html

```
Temporary = ESP;
```

```
Push(EAX);
```

```
Push(ECX);
```

```
Push(EDX);
```

```
Push(EBX);
```

```
Push(Temporary);
```

```
Push(EBP);
```

```
Push(ESI);
```

```
Push(EDI);
```

The end result: call trap()

```
3254 alltraps:  
3255 # Build trap frame.  
3256 pushl %ds  
3257 pushl %es  
3258 pushl %fs  
3259 pushl %gs  
3260 pushal  
3261  
3262 # Set up data and per-cpu segments.  
3263 movw $(SEG_KDATA<<3), %ax  
3264 movw %ax, %ds  
3265 movw %ax, %es  
3266 movw $(SEG_KCPU<<3), %ax  
3267 movw %ax, %fs  
3268 movw %ax, %gs  
3269  
3270 # Call trap(tf), where tf=%esp  
3271 pushl %esp  
3272 call trap
```

```

3351 trap(struct trapframe *tf)
3352 {
...
3363     switch(tf->trapno){
3364     case T_IRQ0 + IRQ_TIMER:
3365         if(cpu->id == 0){
3366             acquire(&tickslock);
3367             ticks++;
3368             wakeup(&ticks);
3369             release(&tickslock);
3370         }
3372         break;
...
3423     if(proc && proc->state == RUNNING
            && tf->trapno == T_IRQ0+IRQ_TIMER)
3424         yield();

```

All interrupts, e.g.
 timer interrupt end
 up in a single
 function: trap()

```
3351 trap(struct trapframe *tf)
3352 {
3353     if(tf->trapno == T_SYSCALL){
3354         if(proc->killed)
3355             exit();
3356         proc->tf = tf;
3357         syscall();
3358         if(proc->killed)
3359             exit();
3360     }
3361     return;
3362
3363     switch(tf->trapno){
3364         case T_IRQ0 + IRQ_TIMER:
```

Same for syscalls

syscall(): get the number from the trap frame

```
3625 syscall(void)
3626 {
3627     int num;
3628
3629     num = proc->tf->eax;
3630
3631     if(num > 0 && num < NELEM(syscalls) && syscalls[num])
3632     {
3633         proc->tf->eax = syscalls[num]();
3634     } else {
3635         sprintf("%d %s: unknown sys call %d\n",
3636                 proc->pid, proc->name, num);
3637         proc->tf->eax = -1;
3638     }
3639 }
```

syscall(): process a syscall from the table

```
3625 syscall(void)
3626 {
3627     int num;
3628
3629     num = proc->tf->eax;
3630     if(num > 0 && num < NELEM(syscalls) && syscalls[num])
3631     {
3632         proc->tf->eax = syscalls[num]();
3633     } else {
3634         sprintf("%d %s: unknown sys call %d\n",
3635             proc->pid, proc->name, num);
3636         proc->tf->eax = -1;
3637     }
3638 }
```

```
3600 static int (*syscalls[])(void) = {  
3601     [SYS_fork] sys_fork,  
3602     [SYS_exit] sys_exit,  
3603     [SYS_wait] sys_wait,  
3604     [SYS_pipe] sys_pipe,  
3605     [SYS_read] sys_read,  
3606     [SYS_kill] sys_kill,  
3607     [SYS_exec] sys_exec,  
3608     [SYS_fstat] sys_fstat,  
3609     [SYS_chdir] sys_chdir,  
3610     [SYS_dup] sys_dup,  
3611     [SYS_getpid] sys_getpid,  
3612     [SYS_sbrk] sys_sbrk,  
3613     [SYS_sleep] sys_sleep,  
3614     [SYS_uptime] sys_uptime,  
3615     [SYS_open] sys_open,  
3616     [SYS_write] sys_write,  
3617     [SYS_mknod] sys_mknod,  
3618     [SYS_unlink] sys_unlink,  
3619     [SYS_link] sys_link,  
3620     [SYS_mkdir] sys_mkdir,  
3621     [SYS_close] sys_close,  
3622 };
```

System call table

How do user programs access system calls?

- It would be weird to write

```
8410    pushl $argv
```

```
8411    pushl $init
```

```
8412    pushl $0 // where caller pc would be
```

```
8413    movl $SYS_exec, %eax
```

```
8414    int $T_SYSCALL
```

- ... every time we want to invoke a system call
- This is an example for the exec() system call

```
// system calls  
  
int fork(void);  
  
int exit(void) __attribute__((noreturn));  
  
int wait(void);  
  
int pipe(int*);  
  
int write(int, void*, int);  
  
int read(int, void*, int);  
  
int close(int);  
  
int kill(int);  
  
int exec(char*, char**);

...
```

user.h

- user.h defines system call prototypes
- Compiler can generate correct system call stacks
 - Remember calling conventions?
 - Arguments on the stack

Example

- From cat.asm
- if (write(1, buf, n) != n)

A3:	53	push	ebx
a4:	68 00 0b 00 00	push	0xb00
a9:	6a 01	push	0x1
ab:	e8 c2 02 00 00	call	372 <write>

- Note, different versions of gcc
 - and different optimization levels
- Will generate slightly different code

Example

- From cat.asm
- if (write(1, buf, n) != n)

a0:	89 5c 24 08	mov %ebx, 0x8(%esp)
a4:	c7 44 24 04 00 0b 00	movl \$0xb00, 0x4(%esp)
ab:	00	
ac:	c7 04 24 01 00 00 00	movl \$0x1, (%esp)
b3:	e8 aa 02 00 00	call 362 <write>

Example

- From cat.asm
- if (write(1, buf, n) != n)

a0:	89 5c 24 08	mov %ebx, 0x8(%esp)
a4:	c7 44 24 04 00 0b 00	movl \$0xb00, 0x4(%esp)
ab:	00	
ac:	c7 04 24 01 00 00 00	movl \$0x1, (%esp)
b3:	e8 aa 02 00 00	call 362 <write>

Example

- From cat.asm
- if (write(1, buf, **n**) != n)

a0: 89 5c 24 08

mov %ebx,0x8(%esp)

a4: c7 44 24 04 00 0b 00

movl \$0xb00,0x4(%esp)

ab: 00

ac: c7 04 24 01 00 00 00

movl \$0x1,(%esp)

b3: e8 aa 02 00 00

call 362 <write>

- Still not clear...
 - The header file allows compiler to generate a call side invocation,
 - e.g., push arguments on the stack
 - But where is the system call invocation itself
 - e.g., `int $T_SYSCALL`

```
8450 #include "syscall.h"
8451 #include "traps.h"
8452
8453 #define SYSCALL(name) \
8454     .globl name; \
8455     name: \
8456         movl $$SYS_ ## name, %eax; \
8457         int $T_SYSCALL; \
8458     ret
8459
8460 SYSCALL(fork)
8461 SYSCALL(exit)
8462 SYSCALL(wait)
8463 SYSCALL(pipe)
8464 SYSCALL(read)
```

usys.S

- Xv6 uses a **SYSCALL** macro to define a function for each system call invocation
 - E.g., `fork()` to invoke the “`fork`” system call

Example

- Write system call from cat.asm

00000362 <write>:

SYSCALL(write)

362:	b8 10 00 00 00	mov	\$0x10,%eax
367:	cd 40	int	\$0x40
369:	c3	ret	

System call arguments

- Where are the system call arguments?
- How does kernel access them?
 - And returns results?

Example

- Write system call

- if (write(1, buf, n) != n)

```
5876 int
5877 sys_write(void)
5878 {
5879     struct file *f;
5880     int n;
5881     char *p;
5882
5883     if(argfd(0, 0, &f) < 0 || argint(2, &n) < 0 || argptr(1, &p, n) < 0)
5884         return -1;
5885     return filewrite(f, p, n);
5886 }
```

Example

- Write system call

- if (write(1, buf, n) != n)

```
5876 int
5877 sys_write(void)
5878 {
5879     struct file *f;
5880     int n;
5881     char *p;
5882
5883     if(argfd(0, 0, &f) < 0 || argint(2, &n) < 0 || argptr(1, &p, n) < 0)
5884         return -1;
5885     return filewrite(f, p, n);
5886 }
```

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

argint(int n, int *ip)

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

argint(int n, int *ip)

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

- Start with the address where current user stack is (esp)

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

argint(int n, int *ip)

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

- Skip return eip

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

argint(int n, int *ip)

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

- Fetch n'th argument

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

argint(int n, int *ip)

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

fetchint(uint addr, int *ip)

```
3543 // Fetch the nth 32-bit system call argument.  
3544 int  
3545 argint(int n, int *ip)  
3546 {  
3547     return fetchint(proc->tf->esp + 4 + 4*n, ip);  
3548 }
```

```
3515 // Fetch the int at addr from the current process.  
3516 int  
3517 fetchint(uint addr, int *ip)  
3518 {  
3519     if(addr >= proc->sz || addr+4 > proc->sz)  
3520         return -1;  
3521     *ip = *(int*)(addr);  
3522     return 0;  
3523 }
```

fetchint(uint addr, int *ip)

Any idea for what argptr() shall do?

- Write system call

- if (write(1, buf, n) != n)

```
5876 int
```

```
5877 sys_write(void)
```

```
5878 {
```

```
5879     struct file *f;
```

```
5880     int n;
```

```
5881     char *p;
```

```
5882
```

```
5883     if(argfd(0, 0, &f) < 0 || argint(2, &n) < 0 || argptr(1, &p, n) < 0)
```

```
5884         return -1;
```

```
5885     return filewrite(f, p, n);
```

```
5886 }
```

- Remember, buf is a pointer to a region of memory
 - i.e., a buffer
 - of size n

```
3550 // Fetch the nth word-sized system call argument as a pointer  
3551 // to a block of memory of size n bytes. Check that the pointer  
3552 // lies within the process address space.
```

```
3553 int  
3554 argptr(int n, char **pp, int size)
```

```
3555 {  
3556     int i;
```

```
3557
```

```
3558     if(argint(n, &i) < 0)  
3559         return -1;  
3560     if((uint)i >= proc->sz || (uint)i+size > proc->sz)  
3561         return -1;  
3562     *pp = (char*)i;  
3563     return 0;  
3564 }
```

- Check that the pointer to the buffer is sound

argptr(uint addr, int *ip)

```
3550 // Fetch the nth word-sized system call argument as a pointer  
3551 // to a block of memory of size n bytes. Check that the pointer  
3552 // lies within the process address space.  
  
3553 int  
3554 argptr(int n, char **pp, int size)  
3555 {  
3556     int i;  
3557  
3558     if(argint(n, &i) < 0)  
3559         return -1;  
3560     if((uint)i >= proc->sz || (uint)i+size > proc->sz)  
3561         return -1;  
3562     *pp = (char*)i;  
3563     return 0;  
3564 }
```

- Check that the buffer is in user memory

argptr(uint addr, int *ip)

Summary

- We've learned how system calls work

Thank you
